Multilevel Models

Mark Andrews Psychology Department, Nottingham Trent University

Multilevel data: Example 1

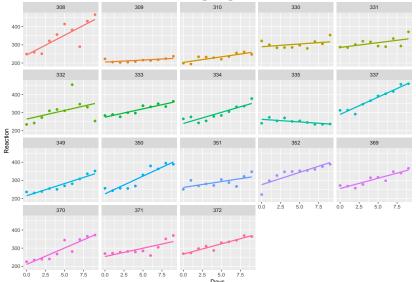

Reaction times¹ for 16 subjects.

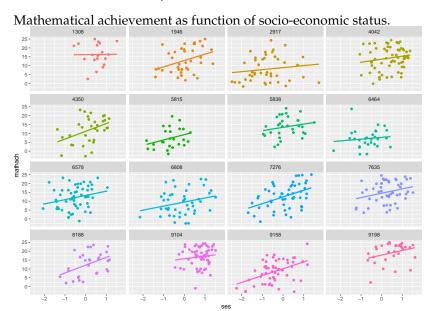

¹This is fake data. Real reaction times would not look so normal.

Multilevel data: Example 2

Reaction time as a function of sleep deprivation.

Multilevel data: Example 3

► Consider we have reaction time data from J subjects,

$$\{x_{j1}, x_{j2}, x_{j3} \dots x_{jn_j}\}_{j=1}^{J}$$
.

► A simple multilevel model for this data might be:

$$\begin{split} &x_{j\,i} \sim N(\mu_j, \sigma^2), \quad \text{for } i \in \{1 \dots n_j\}, \\ &\mu_j \sim N(\theta, \tau^2), \quad \text{for } j \in \{1 \dots J\}. \end{split}$$

- In words, each x_{ji} is drawn from a Gaussian with mean $μ_j$ and variance $σ^2$, and each $μ_j$ is drawn from a Gaussian with mean θ and variance $τ^2$.
- A Bayesian model will put a prior over θ and τ, and infer the posterior over θ, τ, $\mu_1 \dots \mu_J$, σ^2 .

• We can re-write $x_{ji} \sim N(\mu_j, \sigma^2)$ as

$$x_{\text{ji}} = \mu_{\text{j}} + \varepsilon_{\text{ji}}, \quad \varepsilon_{\text{ji}} \sim N(0, \sigma^2). \label{eq:xji}$$

• We can re-write $\mu_j \sim N(\theta, \tau^2)$ as

$$\mu_j = \theta + \eta_j, \quad \eta_j \sim N(0, \tau^2).$$

► The multilevel model can be re-written

$$x_{j\mathfrak{i}} = \theta + \eta_{j} + \varepsilon_{j\mathfrak{i}} \quad \varepsilon_{j\mathfrak{i}} \sim N(0,\sigma^{2}), \eta_{j} \sim N(0,\tau^{2}).$$

► This is often termed a *random-effects* model.

- ightharpoonup The variable θ denotes the global average reaction time.
- ► The variables $\mu_1 \dots \mu_j \dots \mu_J$ are the subjects's average reaction times.
- ► The variables $\eta_1 \dots \eta_j \dots \eta_J$ are the offsets of each subject's average reaction time from the global average. Each $\eta_j = \mu_j \theta$.
- ightharpoonup The variable σ^2 denotes the variance within any given subject.
- ightharpoonup The variable ightharpoonup denotes the variance across subjects.

- ightharpoonup In the model just described, θ tells us the global average.
- The variance τ^2 tells us how much any given subject's average varies about θ.
- ► For example, 95% and 99% of the averages for individual subjects, will be in the ranges

$$\theta \pm 1.96 \times \tau$$
, $\theta \pm 2.56 \times \tau$,

respectively.

Likewise, 95% and 99% of any given subject's reaction times, i.e. x_{ji} , will be in the ranges

$$\theta + \eta_{j} \pm 1.96 \times \sigma$$
, $\theta + \eta_{j} \pm 2.56 \times \sigma$.

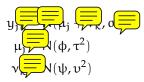

Example: Multiple drivers, multiple cars

- Let's say we want to measure the mpg of a given model of car (e.g. a Porsche 911).
- ▶ Because any one car could vary from others of the same model, we have K different examples of this model of car.
- ► Likewise, because any one driver could affect the recorded mpg of the car he drives, we have J different drivers.
- ► We get each of the J drivers to drive each of the K cars, and record the mpg as

 $y_{jk} = mpg$ for driver j, car k.

Example: Multiple drivers, multiple cars

► A multilevel model for this mpg experiment could be

which would work out as

$$y_{jk} = \underbrace{\theta}_{\phi + \psi} + \eta \zeta + \zeta \zeta + \varepsilon \zeta \zeta = 0$$

with

$$\eta_j \sim N(0,\tau^2), \; \zeta_k \sim N(0,\upsilon^2), \; \varepsilon_{jk} \sim N(0,\sigma^2).$$

Example: Multiple drivers, multiple cars

▶ In this example, we have three sources of variation

$$y_{jk} = \theta + \underbrace{\eta_j}_{\text{within driver}} + \underbrace{\zeta_k}_{\text{within car}} + \underbrace{\varepsilon_{jk}}_{\text{within trial}},$$

where τ^2 gives the within driver variance, v^2 gives the within car variation, and σ^2 gives within trial variation.

- The variable θ provides the average mpg for the car model (i.e. the Porsche 911)
- The variables τ^2 , ν^2 and σ^2 provide measures of the relative variation across in mpg drivers, cars and trials, respectively.

Example: Reaction time and math achievement

- ▶ In this problem, we have J subject. For subject j, we have n_j data points.
- ▶ In observation i from subject j, their number of days without sleep is x_{ji} and the reaction time is y_{ji} .
- ► A multilevel model for this data is

$$\begin{split} y_{ji} &\sim N(\alpha_j + \beta_j x_{ji}, \sigma^2), \\ \alpha_j &\sim N(\alpha, \tau_a^2), \\ \beta_j &\sim N(b, \tau_b^2). \end{split}$$

Example: Reaction time and math achievement

▶ The model

$$\begin{aligned} y_{ji} &\sim N(\alpha_j + \beta_j x_{ji}, \sigma^2), \\ \alpha_j &\sim N(\alpha, \tau_a^2), \\ \beta_j &\sim N(b, \tau_b^2), \end{aligned}$$

can be re-written

$$y_{\mathfrak{j}\mathfrak{i}} = \underbrace{(\mathfrak{a} + \mathfrak{\eta}_{\mathfrak{j}})}_{\alpha_{\mathfrak{j}}} + \underbrace{(\mathfrak{b} + \zeta_{\mathfrak{j}})}_{\beta_{\mathfrak{j}}} x_{\mathfrak{j}\mathfrak{i}} + \varepsilon_{\mathfrak{j}\mathfrak{i}},$$

or

$$y_{ji} = \underbrace{\alpha + \nu \sigma x_{ji}}_{\text{Fived effect}} + \underbrace{\eta_j + \zeta_j x_{ji}}_{\text{Fandom effect}} + \varepsilon_{ji},$$

where

$$\eta_j \sim N(0,\tau_0^2), \ \zeta_j \sim N(0,\tau_0^2), \ \varepsilon_j \sim N(0,\sigma^2).$$

Example: Reaction time and math achievement

- ► In the model just described, a and b are the general regression coefficients.
- The variance τ_a^2 tells us how much variation in the intercept term there is across schools. The variance τ_b^2 tells us how much variation in the slope term there is across schools.
- ► For example, 95% and 99% of the intercepts for individual schools will be in the ranges

$$a \pm 1.96 \times \tau_{\alpha}$$
, $a \pm 2.56 \times \tau_{\alpha}$,

respectively. Likewise, 95% and 99% of the slope terms for schools will be in the ranges

$$b \pm 1.96 \times \tau_b$$
, $b \pm 2.56 \times \tau_b$.
